(54) Title: SENSOR PLATFORM, APPARATUS INCORPORATING THE PLATFORM, AND PROCESS USING THE PLAT-  
FORM

(57) Abstract: A sensor platform for use in sample analysis comprises a substrate (30) of refractive index ( $n_1$ ) and a thin, optically transparent layer (32) of refractive index ( $n_2$ ) on the substrate, ( $n_2$ ) is greater than ( $n_1$ ). The platform incorporates one or multiple corrugated structures in the form of periodic grooves (31), (33), which defines one or more sensing areas each for one of more capture elements. The grooves are so profiled, dimensioned and oriented that when coherent light is incident on the platform it is diffracted into individual beams or diffraction order resulting in reduction of the transmitted beam and an anomalous high reflection of the incident light thereby creates an enhanced evanescent field at the surface of the or each sensing area. The amplitude of this field at the resonant condition is greater by an order of approximately 100 than the field of prior art platforms so that the luminescence intensity created from samples on the platform is also increased by a factor of 100. Also disclosed is an apparatus incorporating the platform and a method of using the platform.

**Sensor Platform, Apparatus Incorporating the  
Platform, and Process using the Platform**

This invention relates generally to the field of analysing samples and has particular, but  
5 not exclusive, application in the field of affinity sensing for example that known generally as  
DNA, protein, peptide and antibody chip technology. One aspect of the invention is  
concerned with a sensor platform which can be used to analyse samples. Another aspect of  
the invention is concerned with an apparatus which makes use of the sensor platform. A  
further aspect of the invention is concerned with the process for analysing samples which  
10 makes use of the platform.

Techniques for analysing two-dimensional arrays of samples are known. One such  
technique is known as an ELISA assay and is based upon the intense biochemical reaction  
between antibodies and antigens. Special mono or polyclonal antibodies are immobilised on  
substrates and react with complimentary species. Fluorophore labelled markers are added,  
15 activated via enzyme-linked antibodies, and the samples are irradiated with light in order to  
induce fluorescence. The fluorescence is detected and the intensity of the fluorescence is  
indicative of the affinity reaction.

Another known technique is that described in WO98/27430. In this a large number of  
different species are immobilised in an array on a substrate. The species are immobilised on  
20 the substrate by photolithographical means. Fluorophore labelled markers are added to the  
species. A sample is prepared and reacted with the immobilised species and the whole chip is  
scanned with a focused laser beam. Alternatively a sample is prepared and modified with  
fluorophore labelled markers and reacted with the immobilised species and the whole chip is  
scanned with a focussed laser beam. The fluorescent signals are detected by photodetectors  
25 and a 2D pattern is produced. Changes in this pattern between individual samples provide an  
indication of differences in gene expression and therefore provides information about  
pharmacology and toxicology.

Another known technique is that based on evanescent wave sensors. These make use  
of coherent laser light which is trapped in a very thin layer and creates so-called evanescent

electromagnetic fields which extends for a small distance outside the actual physical sensor. This field can interact with molecules attached to the surface of the sensor. This evanescent excitation or interaction is limited to a region very close to the vicinity of the waveguide, typically 0.5 microns for visible light from the surface. The evanescent fields remain localised spatially and do not transfer their stored energy to other regions. The interaction of the laser light with the molecules can be used in a number of different ways. These include:

- 1 Detection of luminescence induced by the evanescent field.
- 2 Detection of changes in refractive index which occur when molecules of a sample bind to capture molecules.
- 10 3 Detection of surface plasmon resonance.

One particular sensor which uses an evanescent field is known as a planar waveguide sensor. The planar waveguide sensor comprises a planar substrate having formed thereon a thin wave guiding layer. Part of the wave guiding layer incorporates a grating onto which laser light is incident and from which the laser light is launched so that it propagates through the waveguide layer to a sensing region remote from the grating. The waveguide sensor can be either used in a mass sensitive mode (cf. 2, 3 above), or with superior sensitivity in combination with luminescence excitation and detection (cf. 1 above). Capture molecules are immobilised on the sensing area and the analyte (sample) is then brought into contact with the sensing area/capture molecules in the presence of added labelled molecules with similar affinity (competition). Alternatively, analyte molecules may bind to immobilised capture molecules and fluorescence labels are introduced by reaction of a further labelled species with the captured analyte molecules. Laser light launched into the waveguiding layer leads to evanescent excitation of the fluorophores which then allows the quantification of the analyte. The emitted fluorescence is detected and the intensity of the fluorescence provides an indication of the interaction that has occurred between affinity partners present in the analyte and the immobilised capture molecules. It should be noted that in this type of arrangement the laser radiation propagates inside the waveguide over relatively long distances and the coupling grating and the sensing areas are geometrically separated. (See WO 95/33197 and WO 95/33198).

EP-0 455 067 A2 describes a planar waveguide sensor exploiting the detecting principle of refractive index changes. The platform shallow grooves formed over the entire platform couple polarised, coherent light into the transparent waveguiding layer where it is coupled out after some distance. The angle of the outcoupled beam changes when analyte molecules bind to capture molecules.

Another example of the refractive index type is given in US-A-5738825. The platform contains individual gratings being in contact with the wells of a microtiter plate.

EP 178 083 discloses Surface Plasmon Resonance (SPR) in which the energy of incoming photons is converted to electrical energy as a surface plasmon wave. The sensor architecture requires a metal layer in contrast to the platform of the present invention, and the amount of reflected light at the critical angle is, or approximates to, zero in contrast with the present invention in which the reflected intensity reaches almost 100%.

All the above techniques suffer from various disadvantages. Some are very slow because each sample has to be excited individually. Others such as the planar waveguide allow excitation of more than one sample at a time, but do not provide entirely reliable results because of fluorescence crosstalk between different capture elements and locally varying excitation light intensities due to losses of the waveguides and local variations of coupled power due to variations of grating coupling efficiencies.

The present invention is concerned with a technique which allows multiple samples to be analysed simultaneously in an extremely sensitive, reliable, and quantitative manner.

In contrast to planar waveguide sensors, the present invention shows no luminescence crosstalk and local light intensities are well defined. The present invention allows true multiplexing, i.e. the transducer requires no stacked substructure (as is the case for planar waveguides) and can be seen as a universal platform, where, depending on the requirements, size and number of recognition elements can be varied within the technical feasible limitations, without requiring changes in the chip structure (corrugated areas and sensing areas are not separated as is the case for planar waveguides). In addition, the invention delivers about 100 fold stronger luminescence intensities compared to prior epifluorescence techniques. The experimental set-up is very simple and requires solely a simple adjustment of

the angle of the incident light beam. The transducers described in the present invention, can be easily adapted to conventional fluorescence microscopes, confocal microscopes, and laser scanners. Furthermore, for transducers with a broad resonance width (defined as Full Width at Half Maximum, FWHM) and a resonance position at or close to normal incidence, angle  
5 adjustments are obsolete.

The production process of the platform is relatively simple (cheap) and the performance of existing systems (i.e. fluorescence scanners, microscopes, fluorescence microtiter plate readers, ...) can be easily increased by modest modifications of the respective set-ups.

10 According to a first aspect of the present invention there is provided a platform for use in sample analysis comprising an optically transparent substrate having a refractive index ( $n_1$ ), a thin, optically transparent layer, formed on one surface of the substrate, said layer having a refractive index ( $n_2$ ) which is greater than ( $n_1$ ), said platform incorporating therein one or multiple corrugated structures comprising periodic grooves which define one or multiple  
15 sensing areas or regions, each for one or multiple capture elements, said grooves being so profiled, dimensioned and oriented that either

- a) coherent light incident on said platform is diffracted into individual beams or diffraction orders which interfere resulting in reduction of the transmitted beam and an anormal high reflection of the incident light thereby generating an enhanced evanescent field at the  
20 surface of the one or multiple sensing areas; or
- b) coherent and linearly polarised light incident on said platform is diffracted into individual beams or diffraction orders which interfere resulting in almost total extinction of the transmitted beam and an anormal high reflection of the incident light thereby generating an enhanced evanescent field at the surface of the one or multiple sensing areas.

25 According to a second aspect of the present invention there is provided a platform comprising an optically transparent substrate having a refractive index ( $n_1$ ), a thin, optically transparent layer, formed on one surface of the substrate, said layer having a refractive index ( $n_2$ ) which is greater than ( $n_1$ ), said platform incorporating in the transparent layer a

corrugated structure substantially over the entire platform, or multiple separate corrugated structures arranged on the platform, said structures comprising substantially parallel periodic grooves which are mono- or multi-diffractive which grooves represent one or multiple sensing areas or regions, wherein

- 5 (a) the depth of the grooves is in the range of 3 nm to the thickness of the optically transparent layer,
- (b) the thickness of the optically transparent layer is in the range of 30 to 1000 nm,
- (c) the period of the corrugated structure is in the range of 200 to 1000 nm,
- (d) the ratio of groove depth to the thickness of the optically transparent layer is in the
- 10 range of 0.02 to 1, and
- (e) the ratio of groove width to the period of the grooves is in the range of 0.2 to 0.8. The arrangement may be such that, in use, the grooves are so profiled, dimensioned and oriented that either
- a) coherent light incident on the platform is diffracted into individual beams or diffraction
- 15 orders which interfere resulting in reduction of the transmitted beam and an anomalous high reflection of the incident light thereby generating an enhanced evanescent field at the surface of the one or multiple sensing areas; or
- b) coherent and linearly polarised light incident on said platform is diffracted into individual beams or diffraction orders which interfere resulting in almost total extinction of the
- 20 transmitted beam and an anomalous high reflection of the incident light thereby generating an enhanced evanescent field at the surface of the one or multiple sensing areas.

As used herein, orientation is understood to mean that the electric field vector of the linearly polarised light is parallel or perpendicular to the grooves. As used herein, coherent light is understood to mean that the coherence length of the radiation, i.e. the spatial extent to

25 which the incident beam has a defined phase relation, is large compared to the thickness of the platform.

The evanescent field decays exponentially within wavelength dimensions of the incident beam (less than  $1\mu\text{m}$ ).

An important aspect of the present invention is the use of a platform in which so-called

evanescent resonance can be created. Anormal reflection is a phenomenon which has been described theoretically in the prior art for example in a paper entitled "Theory and applications of guided mode resonance filters" by SS Wang and R Magnusson in Applied Optics, Vol. 32, No 14, 10 May 1993, pages 2606 to 2613 and in a paper entitled "Coupling gratings as  
5 waveguide functional elements" by O.Parriaux et al, Pure & Applied Optics 5, (1996) pages 453-469. As explained in these papers resonance phenomena can occur in planar dielectric layer diffraction gratings where almost 100% switching of optical energy between reflected and transmitted waves occurs when the grooves of the diffraction grating have sufficient depth and the radiation incident on the corrugated structure is at a particular angle. In the present  
10 invention this phenomenon is exploited in the sensing area of the platform where that sensing area includes diffraction grooves of sufficient depth and light is caused to be incident on the sensing area of the platform at an angle such that evanescent resonance occurs in that sensing region. This creates in the sensing region an enhanced evanescent field which is used to excite samples under investigation. It should be noted that the 100% switching referred to above  
15 occurs with parallel beam and linearly polarised coherent light and the effect of an enhanced evanescent field can also be achieved with non-polarised light of a non-parallel focussed laser beam.

At resonance conditions the individual beams interfere in such a way that the transmitted beam is cancelled out (destructive interference) and the reflected beam interferes  
20 constructively giving rise to anormal high reflection.

By choosing appropriate parameters for the above mentioned corrugated layer structure the excitation energy remains highly localized. Such structures are described in the literature as photonic band gap structures, materials with periodic spatial variations of their refractive index such that electromagnetic radiation cannot propagate in any direction. Photonic  
25 bandgap structures allow highly localized modes to appear, see e.g. the paper entitled "Localisation of One Photon States" by C. Adlard, E.R. Pike and S. Sarkar in Physical Review Letters, Vol. 79, No 9, pages 1585-87 (1997). Such structures exhibit extremely large propagation losses corresponding to a mode localisation in the  $\mu\text{m}$  regime.

The platform of the present invention can be considered as optically active in contrast

to optically passive platforms constructed from e.g. a glass or polymer. Here, optically active means increasing the electromagnetic field of the excitation beam by energy confinement.

The substrate of the platform may be formed from inorganic materials such as glass,  $\text{SiO}_2$ , quartz, Si. Alternatively the substrate can be formed from organic materials such as polymers preferably polycarbonate (PC), poly(methyl methacrylate) (PMMA), polyimide (PI), polystyrene (PS), polyethylene (PE), polyethylene terephthalate (PET) or polyurethane (PU). These organic materials are especially preferred for point-of-care (POC) and personalized medical applications since glass is not accepted in such an environment. Plastics substrates can be structured (embossed) much more easily than glass. In one example the substrate is formed from glass.

The optically transparent layer may be formed from inorganic material. Alternatively it can be formed from organic material. In one example the optically transparent layer is a metal oxide such as  $\text{Ta}_2\text{O}_5$ ,  $\text{TiO}_2$ ,  $\text{Nb}_2\text{O}_5$ ,  $\text{ZrO}_2$ ,  $\text{ZnO}$  or  $\text{HfO}_2$ . The optically transparent layer is non-metallic.

Alternatively the optically transparent layer can be made of organic material such as polyamide, polyimide, polypropylene (PP), PS, PMMA, polyacryl acids, polyacryl ethers, polythioether, poly(phenylenesulfide), and derivatives thereof (see for example S S. Hardecker et al., J. of Polymer Science B: Polymer Physics, Vol. 31, 1951-63, 1993).

The depth of the diffraction grooves may be in the range 3 nm to the thickness of the optically transparent layer and preferably 10 nm to the thickness of the optically transparent layer e.g. 30nm to the thickness of the optically transparent layer. The thickness of the optically transparent layer be in the range 30 to 1000 nm, e.g. 50 to 300 nm, preferably 50-200 nm, the period of the corrugated structure may be in the range 200 to 1000 nm, e.g. 200 to 500 nm, preferably 250-500 nm, the ratio of the groove depth to the thickness of the optically transparent layer may lie in the range 0.02 to 1 e.g. 0.25 to 1, preferably 0.3 to 0.7, and the ratio of the grooves width to the period of the grooves ("duty-cycle") may lie in the range 0.2 to 0.8, e.g. 0.4 to 0.6.

The grooves may be generally rectangular in cross-section. Alternatively, the grooves may be sinusoidal or of saw tooth cross-section. The surface structure may be generally

symmetrical. Preferred geometries include rectangular, sinusoidal, and trapezoidal cross-sections. Alternatively, the grooves may be of saw tooth cross-section (blazed grating) or of other asymmetrical geometry. In another aspect the groove depth may vary, e.g. in periodic modulations.

5           The platform may be square or rectangular and the grooves may extend linearly along the platform so as to cover the surface. Alternatively the platform may be disc shaped and the grooves may be circular or linear.

          The grooves may be formed on a surface of the substrate. Alternatively the grooves may be formed on a surface of the optically transparent layer. As a further alternative, grooves  
10       may be formed both on the surface of the substrate which is the interface and on the surface of the optically transparent layer.

          The corrugated surface of a single sensing area may be optimized for one particular excitation wavelength and for one particular type of polarisation. By appropriate means, e.g. superposition of several periodic structures which are parallel or perpendicular one with  
15       another, periodic surface reliefs can be obtained that are suitable for multiple wavelength use of the platform ("multicolour" applications). Alternatively, individual sensing areas on one platform may be optimized for different wavelengths and/or polarization orientations.

          The surface of the optically transparent layer may include one or a plurality of corrugated sensing areas which each may carry one or a plurality of capture elements.

20       Each capture element may contain individual and/or mixtures of capture molecules which are capable of affinity reactions. The shape of an individual capture element may be rectangular, circular, ellipsoidal, or any other shape. The area of an individual capture element is between  $1\ \mu\text{m}^2$  and  $10\ \text{mm}^2$ , e.g. between  $20\ \mu\text{m}^2$  and  $1\ \text{mm}^2$  and preferably between  $100\ \mu\text{m}^2$  and  $1\ \text{mm}^2$ . The capture elements may be arranged in a regular two dimensional array.  
25       The center-to-center (ctc) distance of the capture elements may be between  $1\ \mu\text{m}$  and  $1\ \text{mm}$ , e.g.  $5\ \mu\text{m}$  to  $1\ \text{mm}$ , preferably  $10\ \mu\text{m}$  to  $1\ \text{mm}$ .

          The number of capture elements per sensing area is between 1 and 1,000,000, preferably 1 and 100,000. In another aspect, the number of capture elements to be immobilized on the platform may not be limited and may correspond to e.g. the number of

genes, DNA sequences, DNA motifs, DNA micro satellites. single nucleotide polymorphisms (SNPs), proteins or cell fragments constituting a genome of a species or organism of interest, or a selection or combination thereof. In a further aspect, the platform of this invention may contain the genomes of two or more species, e.g. mouse and rat.

5       The platform may include an adhesion promoting layer disposed at the surface of the optically transparent layer in order to enable immobilisation of capture molecules. The adhesion promoting layer may also comprise a microporous layer (ceramics, glass, Si) for further increasing assay and detection efficacy or of gel layers which either can be used as medium for carrying out the capture element immobilisation and sample analysis, thereby  
10 further increasing the assay and detection efficacy, or which allow separation of analyte mixtures in the sense of gel electrophoresis. The platform may be formed with a plurality of sensing areas or regions, each having its own diffractive grooves.

A feature of the platform of this invention is that light energy entering the optically transparent layer is diffracted out of the layer immediately due to the nature of the corrugated  
15 platform. Therefore no or negligible waveguiding occurs. Typically the propagation distance is 100µm or less, preferably 10µm or less. This is a very surprisingly short distance. The propagation distance is the distance over which the energy of the radiation is reduced to 1/e.

A third aspect of the invention provides apparatus for analysing samples comprising a platform according to said first or second aspect, means for generating a light beam and for  
20 directing the beam so that it is incident upon the platform at an angle which causes evanescent resonance to occur in the platform to thereby create an enhanced evanescent field in the sensing area of the platform, and means for detecting a characteristic of a material disposed on the sensing area of the platform. The range of angles suitable for creating a resonance condition is limited by the angle of total reflection for incident light on the platform. Preferred  
25 angles are less than 45°, e.g. 30° or less, e.g. 20° to 10° or below, e.g. 0.1° to 9.9°. The angle may equal or approximate normal incidence. The light generating means may comprise a laser for emitting a coherent laser beam. Other suitable light sources include discharge lamps or low pressure lamps, e.g. Hg or Xe, where the emitted spectral lines have sufficient coherence length, and light-emitting diodes (LED). The apparatus may also include optical elements for

directing the laser beam so that it is incident on the platform at an angle  $\theta$ , and elements for shaping the plane of polarisation of the coherent beam, e.g. adapted to transmit linearly-polarised light. The angle  $\theta$  may be defined by the expression  $\sin \theta = n \cdot \lambda / \Lambda$  where  $\Lambda$  is a period of the diffractive grooves,  $\lambda$  is the wavelength of the incident light and  $n$  is the effective refractive index of the optically transparent layer.

Examples of lasers that may be used are gas lasers, solid state lasers, dye lasers, semiconductor lasers. If necessary, the emission wavelength can be doubled by means of non-linear optical elements. Especially suitable lasers are argon ion lasers, krypton ion lasers, argon/krypton ion lasers, and helium/neon lasers which emit at wavelengths between 275 and 753 nm. Very suitable are diode lasers or frequency doubled diode lasers of semiconductor material which have small dimensions and low power consumption.

Another appropriate type of excitation makes use of VCSEL's (vertical cavity surface-emitting lasers) which may individually excite the recognition elements on the platform.

The detecting means may be arranged to detect luminescence such as fluorescence.

Affinity partners can be labelled in such a way that Förster fluorescence energy transfer (FRET) can occur upon binding of analyte molecules to capture molecules. The maximum of the luminescence intensity might be slightly shifted relative to the position of highest anormal reflection depending on the refractive index values of the layer system and the corresponding Fresnel Coefficients.

The samples may be used either undiluted or with added solvents. Suitable solvents include water, aqueous buffer solutions, protein solutions, natural or artificial oligomer or polymer solutions, and organic solvents. Suitable organic solvents include alcohols, ketones, esters, aliphatic hydrocarbons, aldehydes, acetonitrile or nitriles.

Solubilisers or additives may be included, and may be organic or inorganic compounds or biochemical reagents such as diethylpyrocarbonate, phenol, formamide, SSC (sodium citrate/sodium chloride), SDS (Sodiumdodecylsulfate), buffer reagents, enzymes, reverse transcriptase, RNAase, organic or inorganic polymers.

The sample may also comprise constituents that are not soluble in the solvents used, such as pigment particles, dispersants and natural and synthetic oligomers or polymers.

The luminescence dyes used as markers may be chemically or physically, for instance electrostatically, bonded to one or multiple affinity binding partners (or derivatives thereof) present in the analyte solution and/or attached to the platform. In case of naturally-occurring oligomers or polymers such as DNA, RNA, saccharides, proteins, or peptides, as well as synthetic oligomers or polymers, involved in the affinity reaction, intercalating dyes are also suitable. Luminophores may be attached to affinity partners present in the analyte solution via biological interaction such as biotin/avidin binding or metal complex formation such as HIS-tag coupling.

One or multiple luminescence markers may be attached to affinity partners present in the analyte solution, to capture elements immobilized on the platform, or both to affinity partners present in analyte solution and capture elements immobilized at the platform, in order to quantitatively determine the presence of one or multiple affinity binding partners.

The spectroscopic properties of the luminescence markers may be chosen to match the conditions for Förster Energy Transfer or Photoinduced Electron Transfer. Distance and concentration dependent luminescence of acceptors and donors may then be used for the quantification of analyte molecules.

Quantification of affinity binding partners may be based on intermolecular and/or intramolecular interaction between such donors and acceptors bound to molecules involved in affinity reactions. Intramolecular assemblies of luminescence donors and acceptors covalently linked to affinity binding partners, Molecular Beacons (S. Tyagi et al., Nature Biotechnology 1996, 14, 303-308) which change the distance between donor and acceptor upon affinity reaction, may also be used as capture molecules or additives for the analyte solution. In addition, pH and potentially sensitive luminophores or luminophores sensitive to enzyme activity may be used, such as enzyme mediated formation of fluorescing derivatives.

Transfluorospheres or derivatives thereof may be used for fluorescence labelling, and chemi-luminescent or electro-luminescent molecules may be used as markers.

Luminescent compounds having luminescence in the range of from 400 nm to 1200 nm which are functionalised or modified in order to be attached to one or more of the affinity partners, such as derivatives of

polyphenyl and heteroaromatic compounds

stilbenes,

coumarines,

xanthene dyes,

5 methine dyes,

oxazine dyes,

rhodamines,

fluoresceines,

coumarines, stilbenes,

10 pyrenes, perylenes,

cyanines, oxacyanines, phthalocyanines, porphyrines, naphthalopcyanines, azobenzene derivatives, distyryl biphenyls,

transition metal complexes e.g. polypyridyl/ruthenium complexes, tris(2,2'-bipyridyl)ruthenium chloride, tris(1,10-phenanthroline)ruthenium chloride, tris(4,7-

15 diphenyl-1,10-phenanthroline) ruthenium chloride and polypyridyl/phenazine/ruthenium complexes, such as octaethyl-platinum-porphyrin, Europium and Terbium complexes may be used as luminescence markers.

Suitable for analysis of blood or serum are dyes having absorption and emission  
20 wavelength in the range from 400 nm to 1000 nm. Furthermore luminophores suitable for two and three photon excitation can be used.

Dyes which are suitable in this invention may contain functional groups for covalent bonding, e.g. fluorescein derivatives such as fluorescein isothiocyanate.

Also suitable are the functional fluorescent dyes commercially available from Amersham Life  
25 Science, Inc. Texas. and Molecular Probes Inc.

Other suitable dyes include dyes modified with deoxynucleotide triphosphate (dNTP) which can be enzymatically incorporated into RNA or DNA strands.

Further suitable dyes include Quantum Dot Particles or Beads (Quantum Dot Cooperation, Palo Alto, CA) or derivatives thereof or derivatives of transition metal complexes which may

be excited at one and the same defined wavelength, and derivatives show luminescence emission at distinguishable wavelengths.

Analytes may be detected either via directly bonded luminescence markers, or indirectly by competition with added luminescence marked species, or by concentration-, distance-, pH-, potential- or redox potential-dependent interaction of luminescence donors and luminescence/electron acceptors used as markers bonded to one and/or multiple analyte species and/or capture elements. The luminescence of the donor and/or the luminescence of the quencher can be measured for the quantification of the analytes.

In the same manner affinity partners can be labelled in such a way that electron transfer or photoinduced electron transfer leads to quenching of fluorescence upon binding of analyte molecules to capture molecules.

Appropriate detectors for luminescence include CCD-cameras, photomultiplier tubes, avalanche photodiodes, photodiodes, hybrid photomultiplier tubes.

The detection means can be arranged to detect in addition changes in refractive index.

The incident beam may be arranged to illuminate the sensing area or all sensing areas on one common platform. Alternatively the beam can be arranged to illuminate only a small sub-area of the sensing area to be analysed and the beam and /or the platform may be arranged so that they can undergo relative movement in order to scan the sensing area of the platform.

Accordingly the detecting means may be arranged in an appropriate way to acquire the luminescence signal intensities of the entire sensing area in a single exposure step. Alternatively the detection and/or excitation means may be arranged in order to scan the sensing areas stepwise.

The apparatus may include a cartridge for location against the sensing area of the platform to bring a sample into contact with the sensing area. The cartridge may contain further means in order to carry out sample preparation, diluting, concentrating, mixing, bio/chemical reactions, separations, in a miniaturised format (see WO 97/02357). The apparatus may include a microtiter type device for containing a plurality of samples to be investigated.

A fourth aspect of the present invention provides a process for analysing a sample or

samples which comprises bringing the sample into contact with the sensing area of a platform according to said first or second aspect, irradiating the platform with a light beam such that evanescent resonance is caused to occur within the sensing area of the platform and detecting radiation emanating from the sensing area. The method may comprise adding fluorescent inducing material to the samples under investigation and sensing fluorescence induced in said samples by excitation of the samples by the enhanced evanescent field. Alternatively the method may comprise adding fluorescence inducing or quenching material to the samples under investigation and/or transfer of the samples under investigation into fluorescing or quenching derivatives and sensing fluorescence induced by said samples bound at the sensing platform by excitation with the enhanced evanescent field.

It is believed to be a novel and inventive concept to provide a sensor platform in which each sensing area or region has attached thereto more than one type of capture element or molecule. This concept applies whether the platform is designed for evanescent resonant mode or a more conventional mode such as waveguiding. Thus, according to another aspect of the present invention there is provided a platform for use in a sample analysis, said platform having one or more sensing areas or regions, each for receiving a capture element or elements which when the platform is irradiated with coherent light can interact to provide an indication of an affinity reaction, wherein each capture element includes two or more types of capture molecule.

The invention will be described now by way of example only with particular reference to the accompanying drawings. In the drawings:

Figure 1 is a schematic illustration of a quality control apparatus for analysing the optical parameters and the evanescent resonance condition of a platform in accordance with the present invention;

Figure 2 is a schematic illustration of a sensor platform in accordance with the present invention;

Figure 3 is a schematic view showing the evanescent field profile in relation to the platform;

Figures 4a and 4b are schematic views showing a chip cartridge;

Figure 5 shows an array layout in one example of the present invention;

Figure 6 shows schematically the layout used to measure fluorescences according to one example of the invention;

Figure 7 shows a comparison of results obtained by a prior art technique and the  
5 present invention;

Figure 8 illustrates alternative forms of platform;

Figures 9a to 9c show fluorescence images obtained after incubation of 30pm PM analyte, regeneration, and 30 pM MM analyte using the present platform under resonance conditions as described in Example 5, and

10 Figure 10 shows fluorescence images and data obtained using the present platform under epifluorescence and resonance conditions as described in Example 6.

The invention will be described in terms of the determination of luminescence excited in samples. This determination involves the use of a sensor platform which constitutes one aspect of the present invention, but it will be appreciated that the use of such a platform is not  
15 necessarily restricted to the particular application to be described. Before describing the platform in detail a description will be given in general terms of the way in which the platform can be used to determine luminescence of samples.

The following are definitions of terms which will be used in the description:

Platform: a whole transducer/chip containing one or a plurality of sensing areas

20 Sensing area: a whole corrugated area capable of creating an evanescent field by a resonance effect and containing one or a plurality of capture elements

Capture element: an individual sensing spot containing one or a variety of species of capture molecules

Capture molecule: an individual molecule capable of an affinity reaction

25 In the following examples all temperatures are in degrees Centigrade and are uncorrected.

Referring to Figure 1 a platform in accordance with an aspect of the present invention is shown at (10) and can receive coherent light from a laser (11), the laser light having been expanded by a set of lenses (12, 14) which produce an expanded and parallel beam (16), and polarised by a polariser (18). As will be explained in more detail later, the platform (10) has a

sensing area to which are attached capture molecules. The wavelength of the light will typically be in the range UV to NIR range, preferably between 350 nm to 1000 nm.

The apparatus also includes a detector (20) which can detect light transmitted through the platform (10), a CCD camera (21) to detect the reflected light and a data processing unit  
5 (22).

In use of the apparatus a highly parallel, expanded, coherent, linearly polarised, laser beam (16) is caused to be incident on the sensing area of the platform (10) and light transmitted through the platform is sensed by detector (20) and the reflected light is recorded by the CCD camera (21). The diameter of the expanded excitation beam exceeds the size of  
10 the platform (10). The angle of incidence of the beam on the platform is adjusted by rotation of the platform until the detector (20) detects effectively no light being transmitted through the platform. This indicates the existence of a resonance position at which evanescent resonance is occurring in the sensing area of the platform. Under this condition, the reflected light intensity recorded by the camera (21) reaches a maximum and the data from the camera is  
15 acquired by the data processing unit (22) for processing.

Turning now to Figure 2 of the drawings, an embodiment of the platform (10) comprises a glass substrate (30) into the top surface of which has been etched a plurality of grooves (31). A layer of optically transparent metal oxide (32) is deposited on the upper surface of the substrate (30) and that layer (32) also has formed therein grooves (33). The  
20 substrate (30) can for example be formed from glass such as glass AF45 produced by Schott and typically has a thickness of 0.5 mm-1.0 mm. It will be appreciated that other organic or inorganic materials can be used for the substrate provided that it is optically transparent.

The optically transparent layer is a dielectric transparent metal oxide film such as  $\text{Ta}_2\text{O}_5$  with a high refractive index of approximately 2.2 at a wavelength of 633 nm, i.e.  
25 significantly higher than the refractive index of the substrate. The thickness of this layer will typically be in the range 50 to 200 nm or greater e.g. 50 to 300 nm. The corrugated structures (31) and (33) have a period in the range of 200-1000 nm, e.g. 200 to 500 nm, typically 250-500 nm. The depth of the corrugated structures/diffraction grooves may be in the range 3 nm to the thickness of the optically transparent layer, preferably 10 nm to the thickness of the

optically transparent layer. The metal oxide can be any of a number of examples such as  $\text{Ta}_2\text{O}_5$ ,  $\text{TiO}_2$ ,  $\text{Nb}_2\text{O}_5$ ,  $\text{ZrO}_2$ ,  $\text{ZnO}$ . or  $\text{HfO}_2$ .

In a platform such as that shown in Figure 2, when a parallel beam of polarised laser light is incident thereon at a particular angle of incidence, an effect known as anormal  
5 reflection occurs within the layer (32). When this effect occurs substantially no light is transmitted through the platform (10) and effectively all the light is reflected within the layer (32) so that the coherent laser light is confined to the very thin layer (32) of metal oxide. The resulting high laser field leaks partially out of the layer (32) creating an evanescent field which evanescently excites fluorescent material which is on the surface or in the close vicinity of the  
10 layer (32). It should be noted that this resonance condition can be achieved only when diffractive grooves (31, 33) having a particular depth or greater are employed and it should also be noted that the radiation losses of such a corrugated structure are very high so that effectively no waveguiding of any electromagnetic radiation in the preferred wavelength range occurs within the layer of metal oxide (32). It is preferred that the depth of the grooves be at  
15 least 10 nm but the evanescent resonance starts to build up with shallower grooves. However, provided that the sample to be investigated is in the vicinity of the layer (32) at which the resonance is created the enhanced evanescent field can be used to excite luminescence such as fluorescence in the sample.

An important feature of the present platform is that the amplitude of this evanescent  
20 field at resonance position is significantly greater than that of the prior art arrangements (epifluorescence corresponding to off-resonance condition) by an order of approximately 100.

This means that the intensity of luminescence, e.g. fluorescence, which can be created from samples is also increased by a factor of 100. The function of the platform can be viewed in terms of the diffractive structure acting as a volume grating which diffracts light and that the  
25 diffractive beams interfere creating a resonance condition where the light reflected from the first interface and light reflected from the top interface that is the upper surface of the layer (32) interfere constructively giving rise to reflection maxima. Under resonance conditions, the laser energy is substantially confined to the thickness of the thin layer (32) thereby increasing the electrical field strength. For a given laser wavelength and period of the corrugated

structure, the resonance is angle-dependent. The angle dependent resonance typically has a width at half maximum height (FWHM) of  $> 0.1^\circ$  preferably  $0.5^\circ$  or greater e.g.  $1.0^\circ$  or greater.

This resonance width is dependent upon the depth of the grooves, the duty cycle and geometry of the corrugated structure. Compared to coupling behaviour of a waveguide grating, the FWHM of the resonance described is greater by many orders of magnitude.

It will be appreciated that the diffraction grooves (31, 33) can be formed on the platform by appropriate conventional techniques. One way of achieving this is to etch the grooves by a photographic technique. In this, a photoresist composition is deposited on the surface of the substrate to a depth of approximately  $1\mu\text{m}$ , a periodic structure corresponding to the groove formation is then written into the resist either by two beam interferometry/holography or by use of a phase mask and then the resist is etched with a reactive ion etching technique using argon gas and finally the residual photoresist material is stripped from the surface. This technique can be used for forming both grooves (31) and grooves (33). Other ways of incorporating the corrugated structures include embossing, electron beam writing, laser ablation, LIGA process.

In order to prepare a platform of the type described with reference to Figure 2 so that it can be used in a measurement such as that illustrated in Figure 6, a number of procedures should be followed.

The first step is to clean the platform to remove impurities from the platform surface.

The cleaning procedure can be achieved by a number of means, for example by means of an ultraviolet cleaner, by plasma cleaning, or by chemical cleaning using materials such as acids, bases, solvents, gases and liquids.

Once the platform has been cleaned the next step is to apply to the surface of the metal oxide layer a layer of an adhesion promoting agent. This layer is applied to the platform since capture elements which are to be deposited on the platform might not readily adhere to the metal oxide layer itself. There are several ways in which this layer can be formed. One way is to form a layer of a network of silane molecules and another way is to use what are known as self-assembled monolayers (SAM). These are known techniques which will be apparent to the person skilled in the art. Silanisation for example which can involve a liquid or gas phase is

described in Colloids and Interface Science 6, L Boksanyi, O Liardon, E Kovats, 1976, 95-237. The formation of self-assembled monolayers is described for example in "Ultra thin organic films" by Abraham Ulman, 1991, Academic Press inc. In addition, there are further methods available for the immobilisation of capture elements such as

- 5 - chemical modification of the chip surface with reactive groups and of the capture molecules with appropriate linkers (U. Maskos and E.M. Southern, Nucleic Acids Research 1992, vol. 20, 1679-84)
- modification of surface and capture molecules with photoreactive linkers/groups (WO 98/27430 and WO 91/16425)
- 10 - Immobilisation via coulombic interaction (EP 0 472 990 A2)
- coupling via tags (for instance proteine-tag, HIS-tag) in chelating reactions
- and various further methods, for instance as described in Methods in Enzymology Academic Press, New York, Klaus Mosbacher (ed.), Vol. 137, Immobilised enzymes and Cells, 1988.
- Plasma induced immobilization/generation of adhesion promoting layers containing
- 15 functional/reactive groups, which enable direct coupling of capture molecules or derivatized capture molecules, or indirect coupling of capture molecules or derivatized capture molecules via chemical linkers or photochemical linkers.

An adhesion promoting layer can for example be produced by silanization with 3-(glycidoxypropyl)trimethoxysilane (GOPTS). Compounds containing nucleophilic groups

20 such as amines can react with the epoxy function of the silane in order to be covalently immobilized. Such a silanization can therefore e.g. be used for immobilization of antibodies which contain multiple amino groups since antibodies consist of amino acids. In addition, DNA/RNA/PNA strands as capture molecules can also be modified with amino groups in order to attach these capture molecules covalently at the platform, as shown in application

25 Example 4 (SNP discrimination). In this example, oligonucleotides with amino function have been covalently immobilized at the surface of the platform. However, other types of capture molecules can be modified for this purpose.

In addition, an adhesion promoting layer can be further chemically modified in order to

alter the surface properties. For example, a GOPTS-silanized platform can be reacted with functionalized saturated or unsaturated organic/hetero-organic/inorganic molecules/derivatives in order to manipulate hydrophobic/hydrophilic balance of the platform, i.e. change the contact angle of the platform. Furthermore, ionic or potentially ionic compounds can be used to  
5 create positive or negative charges at the surface of the platform. Capture molecules can be bound either covalently or by physisorption or by coulombic interaction of charged molecules or by a mixture thereof to such modified surfaces/platforms. This is demonstrated in application Example 2 below, where 3-amino-1-propanol is used to modify the surface characteristics of the GOPTS-silanized platform in a second reaction step in order to  
10 immobilize DNA/RNA/PNA capture molecules. In this example the nitrogen (amine group) introduced at the surface of the platform is quaternized by protons and provides therefore positive charges which interact with negative charges of the DNA (polyelectrolyte nature). Instead of 3-amino-1-propanol also other organic derivatives of amines, e.g. aliphatic amines, or branched aliphatic amines, or amines containing aromatic or non-aromatic cyclic structures,  
15 or amines containing hetero-atoms, or amines containing functional groups, or amines containing combinations thereof can be used for the immobilization of capture molecules, e.g. DNA/RNA/PNA strands.

Functionalized organic molecules can be used which provide hydrocarbon chains to render the platform more hydrophobic, polar groups can be used to render the platform more  
20 hydrophilic, or ionic groups, or potentially ionic groups can be used to introduce charges. For instance Polyethyleneglycol (PEG) or derivatives thereof can be used to render the platform hydrophilic, which prevents non-specific absorption of proteins to the platform/surface.

Reactive or photoreactive groups may be attached to the surface of the platform which may serve as anchor groups for further reaction steps.

25 A SAM as adhesion promoting layer suitable for immobilization of antibodies can be obtained by treatment of the platform with amphiphilic alkylphosphates (e.g. stearyl phosphate). The phosphate headgroup reacts with the hydroxy groups at the surface of the platform and leads to the formation of an ordered monolayer of the amphiphilic alkylphosphates. The hydrophobic alkyl chains render the surface of the platform hydrophobic

and thus enable the physisorption of antibodies, as shown in application Example 6 (multiplexed immunoassays).

A SAM may also be used for the immobilization of other capture molecules, e.g. for DNA/RNA/PNA strands. In this case, amphiphilic phosphates/phosphates modified e.g. with amine groups or epoxy groups can also be used. The capture molecules can be either coupled directly to the SAM, e.g. to an amine-modified SAM, or after the platform has been reacted with organic derivatives of amines, e.g. aliphatic amines, or branched aliphatic amines, or amines containing aromatic or non-aromatic cyclic structures, or amines containing hetero-atoms, or amines containing functional groups, or amines containing combinations thereof, or any other organic, hetero-organic, and /or inorganic molecules (e.g. epoxy modified SAM).

An adhesion promoting layer may consist of multiple layers in order to manipulate surface characteristics, e.g. hydrophobicity, contact angle, charge density. In addition, a layer attached to the platform with any of above mentioned methods may provide or introduce chemical functionality which is required either for the next, subsequent layer, or for the coupling of capture molecules or derivatized capture molecules. An attachment of chemical linker molecules or photochemical linker molecules can also be seen as an intermediate layer which enables the attachment of capture molecules to the platform.

This controlled combination of layers/molecules with different functionalities in general is attributed as Supramolecular Chemistry (J-M. Lehn, Supramolecular chemistry - Scope and perspectives. Molecules, supermolecules, and molecular devices, (Nobel Lecture, 8.12.1987), Angew. Chem. Int. Ed. Engl., 27, 89, 1988.). The obtained supramolecular structure provides a functionality which differs from the functionality of the individual molecules used for the individual layers. For the present invention, an intermediate layer can also introduce luminophors into such a layer system, which can either be used as energy donor or energy acceptor/quencher in the sense of Förster Energy Transfer (FRET) or photoinduced electron transfer, or potential sensitive luminophors, before capture molecules or modified capture molecules are attached to the platform.

For the above-described methods of surface treatment, the following organic or

inorganic molecules and derivatives thereof can be used:

amines, modified amines, jeffamines, aliphatic amines, alcohols, acids, aldehydes, ketones, amides, anhydrides, phosphates, phosphonates, sulfates, sulfonates, thiols, hetero-atom containing compounds, aromatic and aliphatic organic functionalized molecules, aromatic and  
5 aliphatic hetero-organic molecules,  
natural and artificial polymers, silanes, molecules modified with chemical or photochemical active groups, derivatives thereof and functionalized, e.g. omega-functionalized derivatives of the listed species.

In principle, for the build-up of layer structures consisting of one or multiple layers,  
10 chemical reactive groups and/or chemical groups having special physical or electro chemical properties (e.g. charges) are required for the used molecules with all of the above described surface treatments.

Either chemical/photochemical interactions (e.g. addition, nucleophilic/electrophilic substitution, radical reaction, condensation, reactions with organic/hetero-organic/inorganic  
15 carbonyl derivatives, or photo-induced reactions, or thermo-induced reactions, Lewis acid/base concept), and/or

physical/electrochemical interaction (e.g. Coulomb-interaction,  
hydrophobic/hydrophilic interaction), and/or

biologic interaction (e.g. antigene/antibody, hybridization, Streptavidin/Avidin-Biotine  
20 interaction, agonist/antagonist interaction), and/or

photochemical/photophysical interaction  
may be employed for coupling between molecules/components incorporated into such a layer system/adhesion promoting layer.

Adhesion promotion can also be achieved by deposition of microporous layers or gels  
25 on the surface of the platform, the surface characteristics/functionality of the microporous layers or gels facilitating deposition of capture elements shortening the required incubation time and enhancing sensitivity of the subsequent measures. The microporous layers can comprises organic compounds such as polymers, monomers, molecular assemblies and supra molecular assemblies or it can comprise inorganic compounds such as glass, quartz, ceramic,

silicon and semiconductors.

An adhesion-promoting layer may be produced by silanisation e.g. using 3-(glycidoxypropyl)trimethoxysilane (GOPTS). The adhesion promoting layer may be further chemically modified in order to alter the surface properties. For example, a GOPTS-silanized platform may be reacted with functionalized saturated or unsaturated organic molecules in order to manipulate the hydrophobic/hydrophilic balance of the platform, and thereby altering the contact angle of the platform.

Once the adhesion promoting layer has been formed on the platform an additional cleaning step or steps may be necessary to remove excess chemicals used in the preparation of such a layer. After that cleaning the platform is then ready to receive capture elements.

A two dimensional array of capture or recognition elements is formed on the 3-D surface of the adhesion promoting layer previously deposited on the platform. The array of capture elements can be deposited in a variety of ways. Techniques which can be used to deposit capture elements include ink jet printers which have piezoelectric actuators, electromagnetic actuators, pressure/solenoid valve actuators or other force transducers; bubble jet printers which make use of thermoelectric actuators; or laser actuators; ring-pin printers; pin tool-spotters; on-chip-synthesis such as that described in WO90/03382 or WO92/10092; very large scale immobilised polymer synthesis (VLSIPS) such as that described in WO98/27430; photoactivation/photodeprotection of special design photoreactive groups anchored at the surface of the adhesion promoting layer; microcontact printing; microcontact writing pens; drawing pen or pad transfer/stamping of capture elements; microfluidics channels and flowcells made by casting from polymer such as PMMA masters for example using PDMS (polydimethoxysilane) or by micromechanical or mechanical means, or made by etching techniques for local delivery of capture elements; structuring of capture elements by photoablation; or deposition of capture elements onto gel pads using one of the previously mentioned techniques or any other photoimmobilisation technique.

The capture or recognition elements which can be deposited onto the platform are many and varied. Generally speaking the capture molecules used should be capable of affinity reactions. Examples of recognition or capture molecules which can be used with the present

platform are as follows:

nucleotides, oligonucleotides (and chemical derivatives thereof)

DNA (double strand or single strand) a) linear (and chemical derivatives thereof)

b) circular (e.g. plasmids, cosmids, BACs,

ACs)

total RNA, messenger RNA, cRNA, mitochondrial RNA, artificial RNA, aptamers

PNA (peptide nucleic acids)

Polyclonal, Monoclonal, recombinant, engineered antibodies, antigens, haptens,

antibody FAB subunits (modified if necessary)

proteins, modified proteins, enzymes, enzyme cofactors or inhibitors, protein

complexes, lectins, Histidine labelled proteins, chelators for Histidine-tag components

(HIS-tag), tagged proteins, artificial antibodies, molecular imprints, plastibodies

membrane receptors, whole cells, cell fragments and cellular substructures, synapses,

agonists/antagonists, cells, cell organelles, e.g. microsomes

small molecules such as benzodiazapines,

prostaglandins,

antibiotics, drugs, metabolites, drug metabolites

natural products

carbohydrates and derivatives

natural and artificial ligands

steroids, hormones

peptides

native or artificial polymers

molecular probes

natural and artificial receptors

and chemical derivatives thereof

chelating reagents, crown ether, ligands, supramolecular assemblies

indicators (pH, potential, membrane potential, redox potential)

tissue samples (tissue micro arrays)

The activity or density of the capture molecules can be optimised in a number of ways. The platform with the capture elements deposited thereon can be incubated in saturated water vapour atmosphere for a defined period in order to rehydrate the printed loci. This optimises

5 the density of the capture molecules, i.e. increases available binding sites per unit area.

Subsequently the incubated chips can be baked for a defined period, say 1 minute at 80°C for cDNA capture molecules. The platform can be washed by wetting with a small amount of pure water or any other suitable liquids or solutions to avoid cross contamination of the capture elements by excess unbound material. After these procedures, the prepared platform

10 can be stored in a dessicator until use. Prior to use of the chip, an additional washing procedure with 0.1 to 10 ml hybridization buffer or other suitable solutions/liquids may be required to reactivate/rehydrate the dried capture elements and to further remove excess unbound capture elements/buffer residues. In the case of DNA capture molecules, the washing procedure has found to be most effective when performed at a temperature between 50 and  
15 85°C.

Process steps for the chip handling can be automated by using hybridization stations such as e.g. the GeneTAC Hybridization station from Genomic Solutions Inc., Michigan, US.

The particular measurement technique to be described is that involving luminescence in particular fluorescence. In carrying out a measurement, a sample to be investigated is  
20 placed on the sensing area of the platform on which the capture elements have been provided. In order to achieve fluorescence, fluorophores are added to the system prior to the measurement being taken. The fluorophores can be added to the sample for example as labelled affinity partners although it is also possible to attach fluorophores to the capture elements on the platform. The measurements are based upon the fact that fluorescent emission  
25 from the capture elements containing labelled capture molecules and/or from labelled affinity partners is altered by its interaction with the analyte or sample under investigation. Labels of different excitation and emission wavelength can be used, there being one or several different labels, label 1 being for a control experiment and label 2 for the experiment.

Figure 3 shows schematically the energy profile of the evanescent field at resonance

position and how it extends beyond the surface of the metal oxide layer (32) so that it can excite fluorophores in the close vicinity of the surface of the sensing area, e.g. fluorophores attached to capture molecules or fluorophores attached to molecules bound to the capture molecules (38). The evanescent field decreases exponentially to zero within approximately  
5 one micron.

It will be appreciated that in carrying out an analysis one or multiple measurements are made. One can be background measurement prior to the sample being brought into contact with the capture elements. A second measurement can be made with/after the sample has been brought in contact with the capture elements. For comparison of multiple samples, for  
10 instance "control" and "treated" sample in gene expression experiments, the chip can be regenerated after the "control" experiment as described in the application example 2, and a further background measurement and a measurement after/with the "treated" sample (was) applied to the chip can be registered. To gain information regarding the reaction kinetics of the affinity partners, a complete set of measurements can be recorded as a function of  
15 incubation time and/or post-wash time. A typical arrangement for such a measurement is shown in Figure 6. The platform shown in Figure 2 is adjusted to the angle at which evanescent resonance is achieved and a measurement of the fluorescence emitted from the surface of the platform is made using the CCD camera (66). This provides an indication of the fluorescence emitted from each position on the array of capture elements deposited on the  
20 platform. This can be analysed to deduce the affinity of the reactions which have occurred between the capture elements and the sample under investigation.

An arrangement as shown in Figure 6 captures the whole luminescence, e.g. fluorescence, image of the entire platform at one shot without the need of any moving parts during measurement. Such a non-scanning device can be very simple and cheap and is  
25 especially suited for point-of-care application or portable systems. Another typical arrangement confines the coherent laser light down to micrometer dimensions by means of optical elements thereby increasing the electrical field in the focal point and scans the sensing area or areas.

It will be appreciated that a wide variety of samples can be analysed using the present

technique. The sample is generally taken to be the entire solution to be analysed and this may comprise one or many substances to be detected. The sample may be a solution of purified and processed tissue, or other materials obtained from biopsy and examination investigation research and development including sample for diagnostic purposes. The sample may also be  
5 a biological medium, such as egg yolk, body fluids or components thereof, such as blood, serum and urine. It may also be surface water, solution or extracts from natural or synthetic media, such as soils or parts of plants, liquors from biological processes or synthetic liquors.

In order to carry out the measurement, the sample may be introduced into a sample cell of the type shown in Figures 4a and 4b of the drawings. This cell comprises a housing (41)  
10 which is made from a polymer such as PMMA. This polymer has been machined to define a central compartment (44) with dimensions corresponding to the dimensions of the platform. A further depression is formed in the compartment (44) to define a chamber (46) which is sealed around its edge by an O-ring (47). The chamber (46) is open at its top and bottom. Solution to be analysed can be introduced into the chamber (46) within the O-ring (47) through a flow  
15 line (45). Flow within the flow line (45) can be controlled by a valves (43). The cell includes a cover (49) which can be located over and secured to housing (41) to close the top of the cell. The cover (49) includes a window (50) which locates over the compartment (46) and thereby allows radiation to pass through the cover and into the cell (46).

In use of the cell, the housing (41) is located against the surface of the platform which  
20 has the capture elements formed thereon so that the lid (49) is remote from that surface. This brings the compartment (46) into communication with the sensing area of the platform. The sample to be investigated is then fed into the compartment (46) through the flow line (45) so that it is brought into contact with the capture elements on the surface of the platform. A measurement of the fluorescence induced at various capture points is then carried out as  
25 previously described.

Figure 8 illustrates possible alternative forms of the platform.

The sensing elements can be arranged in various ways, for instance rectangular, circular, hexagonal-centric, elipsoidal, linear or labyrinthine. The sensing area may be rectangular, round or of any other shape. The grooves may be arranged either equidistant

linear or equidistant circular, or may correspond to segments of such structures.

The platform can be either rectangular or disc-shaped, or of any other geometry. The platform can comprise one or multiple sensing areas, each sensing area can comprise one or multiple capture elements, and each capture element can comprise one or multiple labelled or  
5 unlabelled capture molecules.

The platform can also be adapted to microtiter-type plates/devices in order to perform one or multiple assays in the individual microtiter wells. This can be achieved for all plate types: 96, 384, 1536, or higher numbers of wells, independently of the dimensions of the respective microtiter-plate.

10 The following is a specific example of a platform:

1. Physical performance of 3-D platform: anormal reflection

1a. Platform 1

The gene chip transducer platform comprises a planar, transparent substrate (glass  
15 AF45 by Schott) of 0.7 mm thickness. Into the substrate a periodic surface structure is etched by photolithographical means (deposition of photoresist,  $<1\ \mu\text{m}$ ; writing of periodic structure into resist either by two beam interferometry/holography; etching the resist with reactive ion etching using Ar gas; stripping of residual photoresist).

The shapes of the surface structure are close to sinusoidal. The width (period) of a  
20 single structure is 360 nm. The depth of the grooves are approximately 38 nm.

On top of the homogeneously structured glass surface a dielectric transparent metal oxide film ( $\text{Ta}_2\text{O}_5$ ) with high refractive index of app. 2.2 at 633 nm wavelength is deposited. The process is by ion plating. The layer thickness is 130 nm. The primary  
structure/architecture of the glass surface is transferred to the top of the metal oxide layer due  
25 to the highly energetic and anisotropic deposition process.

When a highly parallel, expanded, coherent laser beam is directed onto the transducer at distinct angles  $\theta$ , corresponding to a so-called resonance position, almost all light is reflected by the transducer platform and the 0. order transmission intensity is reduced to less than 1% (compared to 90-95% at an arbitrary angle).

The width  $\Delta\theta$  of the resonance condition, where almost all the light is reflected, is proportional to the wavelength  $\lambda$  (633 nm, fixed) and to the radiation loss coefficient  $\alpha$ . The radiation loss coefficient is governed by the depth of the grating grooves, geometry and duty cycle of the corrugated structure, and increases almost quadratically with increasing groove depths. For our case (laser wavelength 633 nm, 130 nm metal oxide layer, 38 nm groove depth) the radiation loss is app. 2000/cm, i.e. the propagation distance of a guided laser beam in such a layer system before it is diffracted out of the platform by the periodic structure is 1/2000 cm, = 5  $\mu$ m. This is a surprisingly short distance. Therefore under these conditions no waveguiding occurs. By refinement of the platform specifications the propagation distance can be further reduced.

For characterization of the resonance effect, the intensity of the parallel beam (TE polarisation) is adjusted to 100  $\mu$ W for a 4 mm diameter area (power meter Newport NRC 1835). The angle between platform normal and incident beam is rotated 1 to 2 degrees away from the centre position of the anomalous reflection (resonance condition). The centre position is at 2.5°. The platform is then rotated in steps of 5/1000° (Newport NRC controller PM 500) and the change of the power of the transmitted beam monitored. At resonance angle, less than 1% (< 1  $\mu$ W) of the original transmitted beam reaches the detector. The power of the incident laser beam is reflected totally (specularly reflected beam: approximately 100%).

The full width at half maximum of the resonance for anomalous reflection (FWHM) is in our case 0.9°. The homogeneity of the reflection over the whole transducer surface (18 mm x 18 mm) is better than 90%.

#### 1b. Platform 2

The shapes of the surface structure are close to rectangular. The width (period) of a single structure is 360 nm. The depth of the grooves are approximately 52 nm. On top of the homogeneously structured glass surface a dielectric transparent metal oxide film (Ta<sub>2</sub>O<sub>5</sub>) with high refractive index of approximately 2.15 at 633 nm wavelength is deposited. The process is by sputtering. The layer thickness is 150 nm. The primary structure/architecture of the glass surface is transferred to the top of the metal oxide layer due to the highly energetic and

anisotropic deposition process.

When a highly parallel, expanded, coherent laser beam is directed onto the transducer at distinct angles  $\theta$  corresponding to a resonance position, almost all light is reflected by the transducer platform and the 0. order transmission intensity is reduced to less than 1%

5 (compared to 90-95% at an arbitrary angle).

The width  $\Delta\theta$  of the resonance condition, where almost all the light is reflected, is proportional to the radiation loss coefficient  $\alpha$ . The radiation loss coefficient for our case (laser wavelength 633 nm, 150 nm metal oxide layer, 52 nm groove depth) is above 2000/cm, i.e. the propagation distance of light launched into such a layer system before it is diffracted  
10 out of the platform by the periodic structure is  $1/2000 \text{ cm.} = 5\mu\text{m}$ . Therefore under these conditions no waveguiding occurs.

For the characterization of the resonance effect, the intensity of the parallel beam (TE polarisation) is adjusted to  $600 \mu\text{W}$  for a 4 mm diameter area (power meter Newport NRC 1835). The angle between platform normal and incident beam is rotated 4 degrees away from  
15 normal incidence. The platform is then rotated in steps of  $5/1000^\circ$  (Newport NRC controller PM 500) and the change of the power of the transmitted beam monitored. At resonance angle, less than 0.5% ( $<3\mu\text{W}$ ) of the original transmitted beam reaches the detector. The power of the incident laser beam is reflected totally (specularly reflected beam approximately 100%).

Due to the widening of the resonance width of platform 2 according to deeper grooves  
20 compared to platform 1 the resonance curves of the +1 and -1 diffraction order overlap creating a single extremely wide resonance located exactly at normal incidence. The full width at half maximum of the resonance for anormal reflection (FWHM) is in our case  $4.2^\circ$ . The homogeneity of the reflection over the whole transducer surface (18 mm x 18 mm) is better than 95%.

25

## 2. Example for gene expression analysis

### a) Preparation

Sensor platforms (dimensions  $18 \times 18 \text{ mm}^2$ ) of the type described with reference to figure 2 were first sonicated twice in chloroform (FLUKA, „purriß.“) and subsequently twice in

isopropanol (Merck, „Uvasol“), each for 15 min. The platform were then dried in vacuum and cleaned in a UV cleaner for 30 min (Boeckel industries Inc, model 135500). O-xylene was heated to 75 °C (stirring) and 2 % v/v 3-glycidoxypopyl trimethoxysilane (Fluka, „purum“) as well as 0.2 % v/v N-ethyl-diisopropylamine (Fluka, „purum“) were added to the heated solvent  
5 (stirring). The platforms were mounted into racks and then incubated for 7 h in the solution at 75 °C (stirring). Subsequently, the platforms were sonicated three times in fresh acetonitrile (Fluka, „HPLC grade“), each for 15 min. The platforms were then sonicated in a solution of 2% v/v 3-amino-1-propanol (Fluka, „purum“) in acetonitrile for 15 min and then incubated in the same solution over night at room temperature (stirring). Next day, the platforms were first  
10 sonicated three times for 15 min in fresh isopropanol (Fluka, „HPLC grade“) and then three times for 15 min in fresh methanol (Merck, „Uvasol“). Finally, the platforms were dried and stored in vacuum.

#### **b) Immobilization of recognition elements**

15 Arrays consisting of 10 different cDNAs (each cDNA 10 replicates: CYP 450 1A1, CYP 450 2B1 EST., CYP 450 2B1, CYP 450 2B2, CYP 450 3A1 human, CYP 450 3A2, CYP 450 4A1,  $\beta$ -actin, GAPDH, external standard) were printed on the platforms with an ink-jet printer (Microdrop GmbH, Norderstedt, Germany). The concentration of the cDNA solutions was 50 ng/ $\mu$ L. The diameter (10 ink-jet droplets/position) was about 250  $\mu$ m and pitch of the spots  
20 was about 500  $\mu$ m. Therefore, the overall dimension of the 10x10 arrays was about 5x5 mm<sup>2</sup>. The layout and assignment of the immobilized cDNA spots is schematically shown in Fig. 5. The arrays were printed in the centre of the platforms with the dimensions (18x18mm<sup>2</sup>). Subsequently, the platforms were incubated over night in a closed container in saturated water vapor atmosphere. Next day, the incubated chips can be baked for a defined period, say 1  
25 minute at 80°C. Then the platforms were flushed with deionized water and dried with nitrogen flow.

#### **c) Detection set-up**

The detection set-up used is shown schematically in Fig.6. An excitation laser (61) (HeNe

laser, 633 nm, 1.3 mW) and a 20x beam expander (64) were jointly mounted (62) onto a goniometer (63). The expanded laser beam was directed towards the platform (67) by means of a dichroic mirror (68). The center of rotation for the laser beam lay in the plane of the metal oxide layer of the platform (67). The fluorescence emitted from the platform surface was collected via the dichroic mirror (68). Additional fluorescence filters (65) were used to separate fluorescence (69) from excitation light. A cooled CCD (Astrocam EEV 30/11) camera (66) equipped with a Nikon Noct lens (Numerical Aperture 1.2) was used to measure fluorescence images from the surface platforms. The goniometer allowed the adjustment of the angle of the incident expanded laser beam with respect to the surface normal of the platform. Fluorescence images were taken under evanescent resonance conditions (i.e. the incident expanded laser beam was adjusted to that angle where the light transmitted through the platform shows a minimum).

#### **d) Chip cartridge**

The platform were mounted to the specially designed cartridge (41) made from PMMA/polymer which is schematically shown in Fig. 4. The depression (44) had dimensions (18x18x0.7mm<sup>3</sup>) and the incubation chamber (46) was 0.2mm deep. The solution in the incubation chamber was exchanged via flow channels (45) of 0.5 mm diameter that were drilled into the PMMA. The content of the cartridge was be exchanged via the inlet/outlet (42). The platform was positioned in the corresponding depression of the cartridge with the sensing area directed towards the incubation chamber. The cover (49) was fixed to press the platform against the sealing. The milled/micromachined window (50) in the cover allowed illumination with excitation light and the acquisition of fluorescence images of the platform surface. The valve-to-valve-volume of the cartridge was about 14  $\mu$ L.

#### **e) Denaturation unit**

A thermoelectric element was used to control the temperature for denaturation (79°C), incubation, (42°C) regeneration (79°C) and wash (42°C) of the platform in the flow cartridge.

**f) Sample preparation**

2 groups of rats (each 3 rats) were used for the present study. One group (treated) was treated with 80 mg phenobarbital, sodium salt, in saline (0.9% w/v NaCl) per kg body weight and the second group (control) only with 0.9% NaCl. One daily treatment on 4 consecutive days was given. At the end of the 4 days, the animals were sacrificed and liver samples were snap frozen in liquid nitrogen and stored at  $-80^{\circ}\text{C}$ .

Subsequently, the total RNA/mRNA was isolated and labeled by reverse transcription into first strand cDNA (incorporation of labeled deoxynucleotides, same or different fluorophore labels for control and treated), purified and dissolved in 20  $\mu\text{L}$  hybridization buffer.

**g) Assay processing**

A Cavo stepper syringe was used to pump/aspirate buffers and solutions into the cartridge. The following steps were executed to measure the CYP 450 induction in rat:

- 1) 30 min pre-wash at  $79^{\circ}\text{C}$  with 1 ml hybridization buffer (HB), measurement of *background 1* of the platform in contact with HB.
- 2) Injection of „control“ sample into cartridge, 30 min denaturation at  $79^{\circ}\text{C}$ , then over night incubation at  $42^{\circ}\text{C}$ .
- 3) 10 min post-wash at  $42^{\circ}\text{C}$  with 1mL HB, measurement of „control“ intensities of platform in contact with HB.
- 4) Regeneration: 30 min wash at  $79^{\circ}\text{C}$  with 1 mL hybridization buffer (HB), measurement of *background 2* of the platform in contact with HB.
- 5) Injection of „treated“ sample into cartridge, 30 min denaturation at  $79^{\circ}\text{C}$ , then over night incubation at  $42^{\circ}\text{C}$ .
- 6) 10 min post-wash at  $42^{\circ}\text{C}$  with 1mL HB, measurement of „treated“ intensities of platform in contact with HB.

All fluorescence images were measured under *evanescent resonance conditions*.

**h) Data processing**

The net intensities (*control-background 1* and *treated-background2*) of all spots were calculated and all intensities of the *treated* data set were normalized by the help of the intensities of the external standard. The expression ratios (fold change) between the respective genes were calculated by division of

$$\text{fold change} = \text{normalized treated/control}.$$

Mean values of the each 10 replicates were calculated.

### i) Results

- 10 ER-Chips measured under *evanescent resonance conditions* showed in general about *100 fold stronger intensities* and *improved signal/background ratios*.

The mean values for *fold change* are summarized in the following table:

15

GENE	Fold change
CYP 450 1A1 (rat)	1.6
CYP 450 2B1 EST. (rat)	16
CYP 450 2B1 (rat)	25
CYP 450 2B2 (rat)	32
CYP 450 3A1 (human)	3.2
CYP 450 3A2 (rat)	2.5
CYP 450 4A1 (rat)	1.6
$\beta$ -actin (rat)	2.1
GAPDH (rat)	2.3

### 3. Example to illustrate enhanced amplification

A platform was prepared and processed according to the example just described.

Subsequent to the incubation with sample, 2 images were taken with the CDD camera detection set-up described above with reference to Figure 6. The first image was taken in epifluorescence mode without adjustment to conditions for evanescent resonance („epifluorescence“ in Fig. 7a). The second image was taken under evanescent resonance conditions („ER enhancement“ in Fig. 7b), i.e. the angle of the incident laser beam was adjusted with respect to the surface normal until the light transmitted through the chip showed a minimum. The image profiles (net signals) show that intensities measured with ER-enhancement are about 100 fold stronger than the intensities obtained with conventional epifluorescence.

In the example described above a single sample cell (41) is used to bring the sample into contact with the sensing area of the platform. It will be appreciated that microtiter type sample container can be used in compensation with a platform having a plurality of sensing areas to allow measurement of a plurality of samples and thereby improve measurement efficiency.

#### **4. Oligonucleotide microchip for discrimination of Single Nucleotide Polymorphism (SNP)**

##### *a. Chip Preparation*

Sensor platforms (dimensions 18x18 mm<sup>2</sup>) of the type described with reference to figure 2 were first sonicated twice in chloroform (FLUKA, „purum.“) and subsequently twice in isopropanol (Merck, „Uvasol“), each 15 min. The platforms were then dried in vacuum and cleaned in a UV cleaner for 30 min (Boeckel Industries Inc, model 135500). O-xylene was heated to 75°C (stirring) and 2% v/v 3-glycidoxypopyl-trimethoxysilane (Fluka, „purum“) as well as 0.2% v/v N-ethyl-diisopropylamine (Fluka, „purum“) were added to the heated solvent (stirring). The platforms were then mounted into racks and then incubated for 7 h in the solution at 75°C (stirring). Subsequently, the platforms were washed three times with fresh acetonitrile (Fluka, „HPLC grade“), each for 15 min. Finally the platforms were dried and stored under vacuum.

##### *b. Immobilization of capture elements*

Two different amino-modified oligonucleotides (capture probes) were printed in a checkerboard-like layout (5x5=25 spots) onto the silanized platforms. A GMS 417 ring-pin arrayer was used for the printing (Genetic Microsystems, Boston, MA). The concentration of the oligonucleotides used as capture molecules was 100 nmol/ml. Diameter of the spots was 125 micrometer with 500 micrometer centre-to-centre distance. The 2 oligonucleotides were called cPM ("capture perfect match") and cMM ("capture mismatch") and differ only in one base:

cPM: 3'CACAATTCCACA5'-NH<sub>2</sub>

cMM: 3'CACAACTCCACA5'-NH<sub>2</sub>

cPM and cMM were labeled with an amino group at the 5' end which enables covalent binding of the oligonucleotides to the epoxy-functionalized platforms. The arrays were printed in the centre of the platforms with the dimensions (18x18mm<sup>2</sup>). Subsequently the platforms were incubated over night in a closed container in saturated water vapour atmosphere. Next day the chips were dried and the washed with 1 ml of aqueous 50% urea solution. Alternatively, an aqueous bovine serum albumine solution (BSA, 1 mg/ml) was used. After blocking the chips were flushed with deionized water and then dried with nitrogen flow.

*c. Detection set-up*

The CCD set-up described in the previous example was used.

*d. Chip cartridge*

The cartridge described in the previous example was used.

*e. Analytes/samples*

Two Cy5-labeled oligonucleotides called PM ("perfect match") and MM ("mismatch") with sequences complimentary to the immobilized capture oligonucleotides cPM and cMM were used as the analytes:

PM: Cy5-5'GTGTTAAGGTGT3'

MM: Cy5-5'GTGTTGAGGTGT3'

The concentration of the analyte solutions was 30 pM each.

*f. Assay processing*

A platform was first washed 2 times with 1 ml of hybridization buffer (HB), with 1 min delay between the washings. Subsequently about 15 microliter PM analyte solution (30pM) was injected into the flow cartridge. After 30 min of incubation, the platform was washed with 1 ml of HB and a fluorescence image ("PM" in Fig. 9a) was taken in the resonance position of the chip. Subsequently, the bound fluorescence labeled oligonucleotides were removed (stripped) by injection of 2x1 ml of an aqueous 50% urea solution with 2 min of delay between the injections. After additional 2 min the chip was washed by injection of 2x1ml HB with 2 min delay between the injections and a fluorescence image ("regeneration" in Fig. 9b) was taken in the resonance position of the chip. Finally, approximately 15 microliter MM analyte solution (30pM) was injected into the flow cartridge. After 30 min of incubation, the platform was again washed with 1 ml of HB and a fluorescence image ("MM" in Fig. 9c) was taken in the resonance position of the chip. All steps were performed at room temperature.

*g. Data processing*

The mean intensity of the 2 different groups of capture spots (cPM and cMM) was calculated for both experiments (incubation of 30 pM PM analyte and 30 pM MM analyte). In addition, the difference of the mean intensity cPM-cMM and the ratio cPM/cMM was calculated.

*h. Results*

All data calculated were summarized in the following Table. The two oligonucleotide analytes, Cy-5 labelled PM and Cy-5 labelled MM, which differ only in one base (SNP) can be clearly distinguished from the obtained data.

	30 pM PM analyte mean intensity [counts]	30 pM MM analyte mean intensity [counts]
cPM spots	1140	704
cMM spots	24	2075
cPM-cMM	1116	-1371
cPM/cMM	48	0.34

## 5. Example for antibody immuno assay

Primary antibodies are spatially resolved immobilized (for instance checkerboard pattern) on the surface of the sensor platform. The binding of the antigens to be detected and of the luminescence-labeled secondary antibodies (used for the detection of a second epitope of the individual antigens to be detected) is achieved by subsequent incubation, first with the analyte containing the various antigens in different concentrations, and then with the luminescence-labeled secondary antibodies.

Alternatively, the antigens (analyte) and luminescence-labeled secondary antibodies can be mixed in a pre-incubation step, which allows complexation of luminescence-labeled secondary antibodies with the antigens. After this pre-incubation step, the sensor platform surface is incubated with the mixture.

The luminescence labeled immuno complexes bound to the surface were quantified with the ER-set-up. (Pre-wash with suitable buffer, PBS, and post-wash if required).

## 6. **Protein -microchips for multiplexed immuno assays**

### a. Chip Preparation

Sensor platforms (dimensions 18x18 mm<sup>2</sup>) of the type described above were sonicated twice in chloroform (FLUKA, "puriss.") and subsequently twice in isopropanol (Merck, "Uvasol"), each 15 min. The platforms were dried in vacuum and cleaned in a UV cleaner for 30 min (Boeckel Industries Inc, model 135500). The chips were placed in a small container and stored in a 0.5 mMolar solution of octadecylphosphate in propanol for 24 hours. Subsequently, the chips were washed with 5 ml isopropanol in order to remove excess alkylphosphate and dried in a nitrogen flow. This procedure created a Self-Assembled-Monolayer (SAM) of alkylphosphate at the surface of the platforms. This adhesion promoting layer rendered the platform hydrophobic (contact angle about 100°) and enabled the adsorption of proteins on the platform by hydrophobic interaction.

b. Immobilization of capture elements

Two different monoclonal antibodies, anti-human Chorionic Gonadotropin (anti-hCG) and anti-Interleukin 6 (anti-IL6) were printed in a checkerboard-like layout onto the hydrophobic platforms in saturated water vapour atmosphere (4x4 array, 8 spots for each antibody). The concentration of the capture antibody solutions was 400 and 100 microgramm/ml respectively. An ink-jet-printer was used for the printing (Microdrop, Norderstedt, Germany). The diameter of the spots was 150 micrometer with 320 micrometer centre-to-centre distance. The printed arrays were incubated for 2 hours in a closed container in saturated water vapour atmosphere. Subsequently, the chips were dried and flushed with 10 ml phosphate buffered saline (PBS) solution containing 10% bovine serum albumin (BSA), 5% sucrose and 0.02% sodium azide. This washing step blocked the hydrophobic surface of the chips by adsorption of BSA and rendered the surface more hydrophilic after the capture elements had been immobilized. As a consequence, the blocking procedure prevented non-specific binding of proteins to the platform which could cause increased background fluorescence. After blocking, the chips were flushed with deionized water and dried with nitrogen flow. The platforms were stored in a refrigerator until use.

c. Detection set-up

The CCD set-up described in Example 2 was used.

d. Chip cartridge

The cartridge described in Example 2 was used.

e. Analytes/samples

3 analyte solutions were prepared:

- I) a solution containing 500 ng/ml Cy-5 labelled IL6, antigene
- II) a solution containing 50 ng/ml Cy-5 labelled human Chorionic Gonadotropin (hCG), antigene

III) a preincubated mixture (1 hour) containing 50ng/ml IL6 and 100 ng/ml polyclonal anti-IL6 antibody labelled with Cy5.

PBS pH 7.0 containing 1% BSA is used as solvent for the analytes.

5 f. Assay processing

Three platforms (as described under 6b.) were prepared for the analyte incubation (cf. e.) by mounting the platforms into cartridges and washing with 1 ml of PBS pH 7.0 containing 1% BSA. Subsequently, about 15 microliter of the analyte solutions I), II) and III) were injected into the flow cartridges. The incubation time was 2 hours each for I) and II) . For analyte III)

10 the incubation time was 12 hours. After incubation of the analyte, the platforms were washed with 1 ml of PBS pH 7.0 containing 1% BSA. Fluorescence images were taken from the chips under off-resonance conditions (epi fluorescence, about 7° apart from resonance angle) and under resonance condition for each chip (resonance, incident light about 2.5° with respect to normal). Images and data obtained are shown in Figure 10.

15 All steps were performed at room temperature.

g. Data processing

The mean intensities and the background of the spots were calculated by help of Imagene Array software (Biodiscovery, Los Angeles, CA). Spot mean in Fig. 10 represents the

20 background corrected mean intensity of the respective capture elements under interest. In addition, the noise was calculated as standard deviation of the background from the fluorescence images. Therefore, signal/noise in Fig. 10 corresponds the ratio of spot mean over background standard deviation.

25 h. Results

All data calculated are summarized in Fig. 1a. In Fig 10. Images and data obtained in epifluorescence mode as well as under resonance conditions are summarised in Figure 10. Rows I) and II) show the results of an immunoreaction between immobilized monoclonal capture antibodies and labeled antigens (Cy5-labelled IL6 and hCG respectively).

Row III) corresponds to a sandwich type immuno reaction between an immobilized monoclonal antibody (anti-IL6) and a preincubated mixture of IL6 antigene and a CY5-labelled secondary polyclonal antibody against IL6.

For the results of row I) the signal intensity increases from 46 counts in epi fluorescence mode to 1100 counts in resonance mode of the platform. This corresponds to an enhancement factor of about 24 regarding the spot mean values. The signal/noise ratio improves from 7.0 (epi fluorescence) to 69.2 (resonance), corresponding to a factor of 10.

For the results of row II) the signal intensity increases from 32 counts in epi fluorescence mode to 646 counts in resonance mode of the platform. This corresponds to an enhancent factor of about 20 regarding the spot mean values. The signal/noise ratio improves from 5.0 (epi fluorescence) to 75.1 (resonance), corresponding to a factor of 15.

For the results of row III) the signal intensity increases from 25 counts in epi fluorescence mode to 296 counts in resonance mode of the platform. This corresponds to an enhancent factor of about 12 regarding the spot mean values. The signal/noise ratio improves from 3.8 (epi fluorescence) to 44.1 (resonance), corresponding to a factor of 12.

Spot mean and signal/noise values for all 3 assays are at least one order of magnitude higher for the chips in resonance mode compared to the same chips in non-resonance mode (epi fluorescence). The fluorescence images of rows I) and II) are complementary (checkerboard-layout). All chips used have the same set of capture elements, i.e. monoclonal anti-hCG and monoclonal anti-IL6.

It will be appreciated that many alternatives to the described embodiments are possible.

Another feature of the present platform is that it allows larger sets of data to be acquired in parallel. Also it can be used several times. Immobilised affinity complexes can be regenerated at elevated temperature using organic solvents and/or chaotropic reagents (salt solutions) while maintaining the binding capacity substantially completely.

In the description given above the whole area of a sensing region is irradiated. It is possible also to use a laser with a non-expanded focused beam and to scan the sensing area so that end capture element is excited in turn. This arrangement permits the use of a cheaper photodetector than the CCD camera e.g. a photomultiplier, or avalanche photodiode can be

used. Also this arrangement will enhance further the sensitivity due to the fact that laser energy is more confined.

It is possible also to design platforms in accordance with the present invention for use as microscope slides thereby allowing them to be used with a fluorescence microscope.

5       The platforms can also be designed for use with large scale microfluidic systems such as that described in WO97/02357.

In the above description the use of the platform has been described in application which excite and sense fluorescence. It will be appreciated that the platform can be used in arrangements where affinity reactions are detected by changes of luminescence. It will be also  
10       appreciated that the platform can be used in arrangements where affinity reactions are detected by changes in refractive index.

Platforms in accordance with the present invention can be used in many applications of which the following is a non-exclusive list.

- Gene expression
- 15   - Genomics
- Pharmacogenomics
- Toxicogenomics
- Toxicoproteomics
- Genetics
- 20   - Pharmacogenetics
- Toxicogenetics
- Exon/intron expression profiling
- Human Leukocyte Antigens (HLA) typing
- Analysis of splicing variants
- 25   - Proteomics (on-chip protein assays)
- Patient monitoring (drug, metabolites, and markers)
- Point-of-care, "personalised medicine"
- Diagnostics
- on-chip 2d gels for proteomics or 2d separation in general

- SNP (single nucleotides polymorphism), mini-sequencing
- High Throughput Screening
- Combinatorial chemistry
- Protein-protein interaction
- 5 - Molecular interaction
- Chip-based protein-antibody and peptide interaction
- Green fluorescent protein (GFP)
- in-situ hybridisation
- confocal microscopy
- 10 - fluorescence correlation spectroscopy (FCS)
- conventional microscopy
- MALDI-TOF MS

**Claims**

1. A platform for use in sample analysis comprising an optically transparent substrate having a refractive index ( $n_1$ ), a thin, optically transparent layer, formed on one surface of the substrate, said layer having a refractive index ( $n_2$ ) which is greater than ( $n_1$ ), said platform  
5 incorporating therein one or multiple corrugated structures comprising periodic grooves which define one or multiple sensing areas or regions, each for one or multiple capture elements, said grooves being so profiled, dimensioned and oriented that either
- a) coherent light incident on said platform is diffracted into individual beams or diffraction orders which interfere resulting in reduction of the transmitted beam and an  
10 anormal high reflection of the incident light thereby generating an enhanced evanescent field at the surface of the one or multiple sensing areas; or
- b) coherent and linearly polarised light incident on said platform is diffracted into individual beams or diffraction orders which interfere resulting in almost total extinction of the transmitted beam and an anormal high reflection of the incident light thereby generating an  
15 enhanced evanescent field at the surface of the one or multiple sensing areas.
2. A platform comprising an optically transparent substrate having a refractive index ( $n_1$ ), a thin, optically transparent layer, formed on one surface of the substrate, said layer having a refractive index ( $n_2$ ) which is greater than ( $n_1$ ), said platform incorporating in the transparent  
20 layer a corrugated structure substantially over the entire platform, or multiple separate corrugated structures arranged on the platform, said structures comprising substantially parallel periodic grooves which are mono- or multi-diffractive which grooves represent one or multiple sensing areas or regions, wherein
- (a) the depth of the grooves is in the range of 3 nm to the thickness of the optically  
25 transparent layer,
- (b) the thickness of the optically transparent layer is in the range of 30 to 1000 nm,
- (c) the period of the corrugated structure is in the range of 200 to 1000 nm,
- (d) the ratio of groove depth to the thickness of the optically transparent layer is in the range of 0.02 to 1, and

(e) the ratio of groove width to the period of the grooves is in the range of 0.2 to 0.8.

3. A platform as claimed in claim 2, the arrangement being such that, in use, the grooves are so profiled, dimensioned and oriented that either

5 a) coherent light incident on the platform is diffracted into individual beams or diffraction orders which interfere resulting in reduction of the transmitted beam and an anormal high reflection of the incident light thereby generating an enhanced evanescent field at the surface of the one or multiple sensing areas; or

b) coherent and linearly polarised light incident on said platform is diffracted into  
10 individual beams or diffraction orders which interfere resulting in almost total extinction of the transmitted beam and an anormal high reflection of the incident light thereby generating an enhanced evanescent field at the surface of the one or multiple sensing areas.

4. A platform according to any one of claims 1 to 3 wherein the substrate of the platform  
15 is formed from inorganic material

5. A platform according to any one of claims 1 to 3, wherein the substrate is formed from organic material.

20 6. A platform according to claim 4, wherein the substrate is formed from glass, SiO<sub>2</sub>, quartz or Si.

7. A platform according to claim 5, wherein the substrate is formed from organic polymers such as PP, PC, PMMA, PI, PS, PE, PET or PU.

25

8. A platform according to any one of claims 1 to 3, wherein the optically transparent layer is formed from inorganic material.

9. A platform according to any one of claims 1 to 3, wherein the optically transparent

layer is formed from organic material.

10. A platform according to claim 8, wherein the optically transparent layer is a metal oxide such as Ta<sub>2</sub>O<sub>5</sub>, TiO<sub>2</sub>, Nb<sub>2</sub>O<sub>5</sub>, ZrO<sub>2</sub>, ZnO or HfO<sub>2</sub>.

5

11. A platform according to claim 9, wherein the optically transparent layer is formed from polyamide, polyimide, PP, PS, PMMA, polyacryl acids, polyacryl esthers, polythioether, or poly(phenylenesulfide) and derivatives thereof.

10 12. A platform according to claim 1 or any one of claims 4 to 11 when dependent on claim 1, wherein the depth of the diffraction grooves is in the range 3 nm to the thickness of the optically transparent layer, preferably 10 nm to the thickness of the optically transparent layer.

15 13. A platform according to claim 12, wherein the thickness of the optically transparent layer is in the range 30 to 1000 nm, the period of the diffraction grooves is in the range 200 to 1000 nm, the ratio of the groove depth to the thickness of the optically transparent layer lies in the range 0.02 to 1 and the ratio of the grooves width to the period of the grooves lies in the range 0.2 to 0.8 resulting in an extremely short propagation distance.

20 14. A platform according to any preceding claim, wherein the grooves are generally rectangular in cross-section.

15. A platform according to any one of claims 1 to 13, wherein the grooves are sinusoidal, trapezoidal or of saw tooth cross-section.

25

16. A platform according to any preceding claim, wherein the platform is square or rectangular and the grooves extend linearly along the platform.

17. A platform according to any one of claims 1 to 15, wherein the platform is disc shaped

and the grooves are circular or linear.

18. A platform according to any preceding claim, wherein the grooves are formed on a surface of the substrate.

5

19. A platform according to any one of claims 1 to 17, wherein the grooves are formed on a surface of the optically transparent layer.

20. A platform according to any one of claims 1 to 17, wherein the grooves are formed  
10 both on the surface of the substrate and on a surface of the optically transparent layer.

21. A platform according to any preceding claim, wherein the corrugated surface one or more sensing areas is optimised for a particular excitation wavelength and/or particular type of polarisation.

15

22. A platform according to any one of claims 1 to 20, wherein the corrugated surface of one or more sensing areas is optimised for different wavelength and/or polarisation orientations.

20 23. A platform according to any preceding claim, wherein the surface of the optically transparent layer includes one or a plurality of sensing areas, the or each of which carries one or plurality of capture elements.

24. A platform according to claim 23, wherein each capture element contains individual  
25 and/or mixtures of capture molecules which are capable of affinity reactions.

25. A platform according to claim 23, wherein the capture elements are arranged in a two dimensional array.

26. A platform according to any one of claims 23 to claim 25, including an adhesion promoting layer disposed at the surface of the optically transparent layer in order to enable immobilisation of capture molecules.

27. A platform according to claim 26, wherein the adhesion promoting layer comprises one or multiple layers of inorganic and/or organic molecules or derivatives thereof which provide additional chemical, physical, spectroscopical and/or photophysical photochemical/biological/biochemical properties in order to manipulate the overall functional properties of the resulting adhesion promoting layer system.

28. A platform according to any preceding claim, wherein the platform is formed with a plurality of sensing areas or regions, each having its own diffractive grooves or multiple, superimposed grooves suitable for multicolor excitation and detection of samples.

29. A platform according to any of claims 1 to 23 wherein the number of capture elements or molecules to be immobilized on the platform is not limited and corresponds to the number of genes, DNA sequences, DNA motifs, DNA micro satellites, single nucleotide polymorphisms, proteins or cell fragments which contribute to a genome of a species or organism of interest, or a selection or combination thereof.

30. A platform according to any one of claims 23 to 29 wherein the capture element or elements or molecules comprise one or more of the following:

nucleotides, oligonucleotides (and chemical derivatives thereof)

DNA (double strand, single strand) a) linear (and chemical derivatives thereof)

b) circular (e.g. plasmids, cosmids, BACs, YACs)

total RNA, messenger RNA, cRNA, mitochondrial RNA, artificial RNA, aptamers

PNA (peptide nucleic acids)

Polyclonal, Monoclonal, recombinant, engineered antibodies, antigens, haptens, antibody FAB subunits (modified if necessary)

proteins, modified proteins, enzymes, enzyme cofactors or inhibitors, protein  
 complexes, lectines, Histidine labelled proteins, chelators for Histidine-tag components  
 (HIS-tag), tagged proteins, artificial antibodies, molecular imprints, plastibodies  
 membrane receptors, whole cells, cell fragments and cellular substructures, synapses,  
 5 agonists/antagonists, cells, cell organelles, e.g. microsomes  
 small molecules such as benzodiazapines,  
 prostaglandins,  
 antibiotics, drugs, metabolites, drug metabolites  
 natural products  
 10 carbohydrates and derivatives  
 natural and artificial ligands  
 steroids, hormones  
 peptides  
 native or artificial polymers  
 15 molecular probes  
 natural and artificial receptors  
 and chemical derivatives thereof  
 chelating reagents, crown ether, ligands, supramolecular assemblies  
 indicators (pH, potential, membrane potential, redox potential)  
 20 tissue samples (tissue micro arrays).

31. Apparatus for analysing samples comprising a platform according to any preceding  
 claim, wherein means for generating a light beam and for directing the beam so that it is  
 incident upon the platform at an angle which causes evanescent resonance to occur in the  
 25 platform to thereby create an enhanced resonant field in the sensing area of the platform, and  
 means for detecting a characteristic of a material disposed on or in the vicinity of the sensing  
 area of the platform.

32. Apparatus according to claim 31, wherein the light generating means comprises a laser

for emitting a coherent laser beam.

33. Apparatus according to claim 31, wherein the light generating means comprises a discharge lamp or a low pressure lamp such as a Hg or Xe lamp or a light emitting diode.

5

34. Apparatus according to claim 32, including optical elements for directing the laser beam so that it is incident on the platform at an angle  $\theta$ , the angle  $\theta$  being defined by the expression  $\sin \theta = n \cdot \lambda / \Lambda$  where  $\Lambda$  is a period of the diffractive grooves,  $\lambda$  is the wavelength of the light and  $n$  is the effective refractive index of the optically transmitting layer.

10

35. Apparatus according to any one of claims 31 to 34, wherein the detecting means is arranged to detect luminescence such as fluorescence, phosphorescence, chemi-luminescence, and electro-luminescence.

15 36. Apparatus according to any one of claims 31 and 35, wherein the detection means is arranged to detect in addition or in combination changes in refractive index.

37. Apparatus according to any one of claims 31 to 36, wherein the incident beam is arranged to illuminate all of the or each sensing area.

20

38. Apparatus according to any one of claims 31 to 36, wherein the beam is arranged to illuminate a sub-area of the sensing area to be analysed and the beam and platform are arranged so that they can undergo relative movement to effect scanning of the beam over the sensing area of the platform.

25

39. Apparatus according to any one of claims 31 to 38, including a cartridge for location against the sensing area of the platform to bring a sample into contact with the sensing area.

40. Apparatus according to any one of claims 31 to 38, including a microtiter type device

for containing a plurality of samples to be investigated.

41. A process for analysing a sample or samples which comprises bringing the sample into contact with the sensing area of a platform according to any one of claims 1 to 30, irradiating the platform with a light beam such that evanescent resonance is caused to occur within the sensing area of the platform and detecting radiation emanating from the sensing area.

42. A method according to claim 41, including adding fluorescent inducing material to the samples under investigation and sensing fluorescence induced in said samples by excitation of the samples by the enhanced evanescent field.

43. A process according to claim 41 wherein the fluorescent inducing material comprises a luminescent marker.

44. A process according to claim 43, wherein the luminescent marker comprises luminescent compound or compounds having luminescence in the range of from 400 nm to 1200 nm which are functionalised or modified in order to be attached to one or more of the affinity partners, including derivatives of one or more of the following:

polyphenyl and heteroaromatic compounds

stilbenes,

coumarines,

xanthene dyes,

methine dyes,

oxazine dyes,

rhodamines,

fluoresceines,

coumarines, stilbenes,

pyrenes, perylenes,

cyanines, oxacyanines, phthalocyanines, porphyrines, naphthalocyanines, azobenzene

derivatives, distyryl biphenyls,  
transition metal complexes e.g. polypyridyl/ruthenium complexes, tris(2,2'-  
bipyridyl)ruthenium chloride, tris(1,10-phenanthroline)ruthenium chloride, tris(4,7-  
diphenyl-1,10-phenanthroline) ruthenium chloride and polypyridyl/phenazine/ruthenium  
5 complexes, such as octaethyl-platinum-porphyrin, Europium and Terbium complexes  
quantum dot particles/beads or derivatives thereof.

45. A process according to any one of claims 41 to 44 when used in any one or more of the  
following:

- 10 - Gene expression
- Genomics
- Pharmacogenomics
- Toxicogenomics
- Toxicoproteomics
- 15 - Genetics
- Pharmacogenetics
- Toxicogenetics
- Exon/intron expression profiling
- Human Leukocyte Antigens (HLA) typing
- 20 - Analysis of splicing variants
- Proteomics (on-chip protein assays)
- Patient monitoring (drug, metabolites, and markers)
- Point-of-care, "personalised medicine"
- Diagnostics
- 25 - on-chip 2d gels for proteomics
- SNP (single nucleotides polymorphism), mini-sequencing
- High Throughput Screening
- Combinatorial chemistry
- Protein-protein interaction

- Molecular interaction
- Chip-based protein-antibody and peptide interaction
- Green fluorescent protein (GFP)
- in-situ hybridisation
- 5 - confocal microscopy
- fluorescence correlation spectroscopy (FCS)
- conventional microscopy
- MALDI-TOF MS.

- 10 46. A platform for use in sample analysis, said platform having one or more sensing areas or regions, each for receiving a capture element or elements which when the platform is irradiated with coherent light can interact to provide an indication of an affinity reaction, wherein each capture element includes two or more types of capture molecule.
